

Traffic Safety Basic Facts 2012

Young People (Aged 18-24)

The number of young people killed in road accidents almost halved between 2001 and 2010

In this Basic Fact Sheet, 'young people' are defined as those who are between 18 and 24 years old. In general, young people worldwide are far more likely to be victims in road accidents than people in any other age group.

More than 73.000 persons aged 18-24 years old were killed in traffic accidents, in 20¹ European Union countries within the decade 2001 - 2010. This number represents less than a fifth of all traffic accident fatalities in those countries (18%).

The number of young people killed in road accidents in 2010 almost halved compared to the respective number in 2001. The total number of fatalities also fell by 42% in the 20 European Union countries over the same period.

Figure 1: Distribution of road traffic fatalities in the EU-20¹ 2001-2010²

Source: CARE Database / EC
Date of query: October 2012

¹ See Table "Country abbreviations used and definition of EU-level" on page 21.

² Where a number is missing for an EU-20/23 country in a particular year, its contribution to the EU-20/23 total is estimated as the most recent known value

More than 73.000 persons aged 18-24 years old were killed in road accidents in the EU-20 between 2001 and 2010, less than a fifth of all road accident fatalities in those countries

In 2010, the number of young people killed in Romania was 26% less than in 2009, and the reduction in Greece was over 23%. On the other hand, the number increased in Belgium (16%) and Austria (3%). The most significant reduction in young fatalities between 2001 and 2010 occurred in Slovenia (37%).

Source: CARE Database / EC
Date of query: October 2012

Almost 17% of people killed in road accidents in 2010 in the 23 European countries were aged 18-24. However, only 9% of the population falls within this age group. Young people were at almost twice the average risk of being killed in a road accident across the EU-23 countries in 2010 (this is the relative fatality rate, calculated as the % young people fatalities divided by % young people population).

The most significant reduction in young fatalities between 2001 and 2010 occurred in Slovenia (37%)

As shown in Figure 2, Ireland has the highest relative fatality rate (3,0) whereas Hungary and Portugal have the lowest relative rate (1,1) among the 23 countries in 2010.

Figure 2: Relative fatality rate for young people, 2010²

Figure 4 shows that the highest proportion among the 23 European countries of young people fatalities by mode of transport in 2010 was in Austria (84% were travelling by car/taxi). The second highest proportion of young people fatalities by car/taxi was in Sweden (78%). The lowest car/taxi proportion was in Greece 48% and Slovenia 42%.

49% of the young people fatalities in Greece were riding two-wheelers, the highest proportion among the EU-23 countries

Figure 4: Proportion of young (or 18-24 years old) fatalities by mode of transport, 2010²

Source: CARE Database / EC
Date of query: October 2012

Figure 4 shows that as far as two-wheeler fatalities (users of motorcycles, mopeds or pedal cycles) are concerned, the lowest proportion was in Estonia (5%) and Finland (9%). Greece had the highest proportion of 18-24 year old two-wheeler fatalities (50%) among the 23 countries considered. Estonia had the highest proportion of young people fatalities in lorries (24%). Hungary had the highest proportion of young pedestrian fatalities (19%) whereas Estonia and Slovenia did not have any.

Gender

81% of the fatalities among young people were men. Moreover, males have a significantly higher fatality rate per million population (108), compared to females (25). This can possibly be attributed in part to young men tending to drive farther than young women.

Figure 5: Young people fatality rates per million population, per gender in the EU-23¹, 2010²

Date of query: October 2012

81% of the fatalities
among young
people were men

Area and Road type

In the EU-23, the majority (69%) of young fatalities occurred outside urban areas (excluding motorways) in 2010 and only 7% occurred on motorways. The percentage of young people fatalities inside urban areas was 31% for the EU-23 countries.

Figure 6: Distribution of fatalities amongst young people by area type, 2010²

Source: CARE Database / EC
Date of query: October 2012

Figure 6 shows that in 2010 Estonia had the lowest percentage of young people fatalities inside urban areas (10%) whereas Romania had the highest percentage (54%) amongst the EU-23 countries.

Day of week and Time of day

Figure 7 shows that in 2010 more people aged 18-24 were killed between 06:00 and 20:59 on week-days in the EU-23 countries than between 21:00 and 5:59 (the night-time and early morning).

On the contrary, more young people were killed between 21:00 and 5:59 during the weekends, when young people tend to stay out until late.

Figure 7: Fatality rates per million inhabitants, by day of week and time of day in the EU-23, 2010²

Source: CARE Database / EC
Date of query: October 2012
Source of population data: Eurostat

Estonia had the lowest percentage of young people fatalities inside urban areas (10%) whereas Romania had the highest amongst the EU-23 countries in 2010

On Saturdays and Sundays fatality rates for young people are much higher than the rates for the population as a whole

Table 6 shows that in 2010 in the EU-23 countries, almost half (43%) of the young people who were killed died at the week-end. The proportions are lower between Tuesday and Wednesday.

Date of query: October 2012

The peak period for most of the countries is in July/August, though Denmark, Hungary and Ireland have their peak in March/April, the peak in the Netherlands, Portugal and Belgium is in May/June, while for Czech Republic, Romania, Slovenia, Slovakia and Ireland the peak is in September/October. Fewest fatalities occur in January/February.

In EU-23 the proportion of fatalities aged 18-24 is relatively high in July and August, and relatively low between January and April in 2010.

In the EU-23, the peak period for fatalities in 2010 is July/August (21%)

Figure 8: Distribution of total and young people fatalities by month in the EU-23, 2010²

Source: CARE Database / EC
Date of query: October 2012

Figure 8 shows that the highest proportion of young people fatalities in 2010 occurred in August (11%) in the EU-23 countries whereas the lowest proportion occurred in February (6%). As far as total fatalities are concerned, the highest proportion of total fatalities occurred in July (10%) and in August (10%) whereas the lowest proportion occurred in February (6%).

Accident Causation

During the EC SafetyNet project, in-depth data were collected using a common methodology for samples of accidents that occurred in Germany, Italy, The Netherlands, Finland, Sweden and the UK^{4 5}. The SafetyNet Accident Causation Database was formed between 2005 and 2008, and contains details of 1.006 accidents covering all injury severities. A detailed process for recording causation (SafetyNet Accident Causation System – SNACS) attributes one specific critical event to each driver, rider or pedestrian. Links then form chains between the critical event and the causes that led to it. For example, the critical event of late action could be linked to the cause observation missed, which was a consequence of fatigue, itself a consequence of an extensive driving spell.

In the database, 25% (249) of the accidents involve a driver or rider between 18 and 24 years old. Males account for 75% of this group and 79% are drivers of passenger cars. Figure 9 compares the distribution of specific critical events for drivers and riders of young age against the distribution for 35 to 64 year olds.

⁴ SafetyNet D5.5, Glossary of Data Variables for Fatal and Accident Causation Databases

⁵ SafetyNet D5.8, In-Depth Accident Causation Database and Analysis Report

Figure 9: Distribution of specific critical events - 18 to 24 yr and 35 to 64 yr old drivers/riders

N=1025

Source: SafetyNet Accident Causation Database 2005 to 2008 / EC
Date of query: 2010

The clearest difference between the two age groups relates to the specific critical event of surplus speed, attributed to just over one quarter of the young age group but only 10% of the older group. Surplus speed describes speed that is too high for the conditions or manoeuvre being carried out, travelling above the speed limit and also if the driver is travelling at a speed unexpected by other road users. Incorrect direction is also recorded more frequently for the younger age group. This refers to a manoeuvre being carried out in the wrong direction (for example, turning left instead of right) or leaving the road (not following the intended direction of the road). 'Loss of control' type accidents can fall into either critical event depending on the specific situation.

The specific critical events under the general category of 'timing', no action, premature action and late action, are the next three most frequently recorded events but each is recorded more frequently for the older group, especially no action. No action describes those drivers/riders who have not reacted at all (or at least in an effective time frame) to avoid a collision, for example, to avoid an oncoming vehicle. A premature action is one undertaken before a signal has been given or the required conditions are established, for example entering a junction before it is clear of other traffic. Figure 9 gives the most frequent links between causes for young drivers/riders. For this group there are 371 such links in total.

Table 8: Ten most frequent links between causes – young drivers/riders

Links between causes	Frequency
Inadequate plan - Insufficient knowledge	55
Faulty diagnosis - Information failure (driver/environment or driver/vehicle)	38
Observation missed - Distraction	25
Observation missed - Faulty diagnosis	21
Inadequate plan - Under the influence of substances	18
Observation missed - Temporary obstruction to view	17
Observation missed - Inadequate plan	15
Inadequate plan - Psychological stress	13
Observation missed - Permanent obstruction to view	12
Faulty diagnosis - Communication failure	12
Others	145
Total	371

Source: SafetyNet Accident Causation Database 2005 to 2008 / EC
Date of query: 2010

15% of the links between causes are observed to be between 'inadequate plan' and 'insufficient knowledge'.

Inadequate plan is the most frequently recorded cause and describes a lack of all the required details or that the driver's/rider's ideas do not correspond to reality. The causes leading to inadequate plan are lack of knowledge and impairment from substances and psychological stress.

Faulty diagnosis and observation missed then follow. Faulty diagnosis is an incorrect or incomplete understanding of road conditions or another road user's actions. It is linked to both information failure (for example, a driver/rider thinking another vehicle was moving when it was in fact stopped and colliding with it) and communication failure (for example, pulling out in the continuing path of a driver who has indicated for a turn too early). The causes leading to observation missed can be seen to fall into two groups, human factors (for example, not observing a red light due to distraction) and physical 'obstruction to view' type causes (for example, parked cars at a junction).

ROAD ACCIDENT HEALTH INDICATORS

Injury data can be obtained from a wide range of sources, such as police and ambulance reports, national insurance schemes, and hospital records, each of which provides a specific but yet incomplete picture of the injuries suffered in road accidents. In order to obtain a comprehensive view of these injuries, the EU Council issued a Recommendation that urges member states to use synergies between existing data sources and to develop national injury surveillance systems rooted in the health sector.⁶ At present, thirteen member states are routinely collecting injury data in a sample of hospitals and delivering these data to the Commission. This system is called the EU Injury Database (EU IDB).⁷

Within the EU IDB “transport module” injuries suffered in road accidents are recorded by “mode of transport”, “role of injured person” and “counterpart”. These variables can complement information from police records, in particular for injury patterns and the improved assessment of injury severity. The indicators used include the percentage of casualties attending hospital who are admitted to hospital, the mean length of stay of hospital admissions, the nature and type of body part injured, and potentially also long term consequences of injuries.

Figure 10: Distribution of non-fatal road accident casualties attending hospital, by mode of transport

EU Injury Database (EU IDB AI) - hospital treated patients. IDB AI Transport module and place of occurrence (code 6.n [public road]); n-all = 73 600; n-admitted = 23.568 (DE, DK, LV, MT, AT, NL, SE, SI, CY, years 2005-2008).

Figure 10 is based on IDB data from nine countries for accidents that occurred between 2005 and 2008. Vulnerable road users (pedestrians, cyclists, motorcycles and mopeds) accounted for almost two thirds (63%) of road accident casualties attending hospital, and for over half of casualties admitted to the hospital (56%).

⁶ OJ C 164/1, 18.7.2007

⁷ <https://webgate.ec.europa.eu/sanco/heidi/index.php/IDB>

Overall, 32% of road accident casualties recorded in the IDB were admitted to the hospital, about 30% for youngsters (Figure 3); with an average length of stay of eight days, about six days for youngsters (Figure 2).

Figure 11: Proportion of casualties who were admitted to hospital, by age group and mode of transport

EU Injury Database (EU IDB AI) - hospital treated patients. IDB AI Transport module and place of occurrence (code 6.n [public road]); n-all = 73 600, n-youngsters = 13.190, n- youngsters admitted = 4.336 (DE, DK, LV, MT, AT, NL, SE, SI, CY, years 2005-2008).

Figure 12: Average length of stay (hospital bed days), by age group and mode of transport

Source: See Figure 11

About 30% of injured young people who attended a hospital were admitted to the hospital; their average stay in hospital was six days.

Figure 13: Body part injured in young people (18-24 years), by mode of transport

Source: See Figure 11.

Naturally, hospital data can provide information on the injury patterns sustained by the accident victims. Figure 4 illustrates the distribution of body parts injured in young people's casualties by type of road user.

Table 9 shows the types of injuries most frequently recorded in the EU IDB. It compares the distribution of injuries among young people and road users of all ages.

Table 9: Ten most frequently recorded types of injury, by age group

	Young people (18-24 years)	All age groups
Contusion, bruise	38%	34%
Fracture	18%	27%
Open wound	10%	10%
Distortion, sprain	10%	8%
Concussion	9%	7%
Other specified brain injury	2%	2%
Luxation, dislocation	1%	2%
Injury to muscle and tendon	2%	2%
Abrasion	1%	1%
Injury to internal organs	1%	1%
Other specified types of injury	8%	6%
Total	100%	100%

Source: See Figure 11.

Contusions and bruises account for almost 40% of all traffic injuries suffered by young people attending hospital.
